Venous Thromboembolism Prevention Protocol

This protocol pertains to prevention of VTE in low and high risk pregnant patients admitted as inpatients.

For information about diagnosis and management of women with thrombophilia and VTE see the Thrombophilia Protocol.

Background:

- Pregnant women have increased risk of VTE given venous stasis of lower extremities, endothelial injury and hypercoagulable state of pregnancy.
- Pregnant women are at 5-fold increased risk of VTE compared with non-pregnant women.
- VTE risk increases to over 20-fold intrapartum and postpartum, and risk remains until 12 weeks postpartum.
- VTE risk increases 18 fold during non-delivery hospitalization.
- Accounts for 10% of maternal deaths in developed countries.
- VTE occurs twice as frequently after cesarean delivery compared to vaginal delivery.

Risk of first thromboembolism in and around pregnancy

[Graph showing risk of VTE per 100,000 person years during pregnancy, with peak risk during 39th-40th week and lowest risk postpartum.]

Antepartum Prophylaxis

- Women admitted during pregnancy for antepartum complications need to have mode of VTE prophylaxis considered, documented and implemented. Risk factor status should be assessed and documented (major or minor risk factors) and management strategy devised. It is reasonable to initiate pharmacological VTE prophylaxis on women at time of admission once imminent delivery is felt to be unlikely and women are deemed to have VTE prophylaxis initiated.
- If women are discharged from the antepartum service, the need to continue on VTE prophylaxis will hinge upon whether risk factors are substantial and ongoing and should be determined on an individual basis.
- Women considered low-risk may be have pneumatic compression versus prophylactic dose LMWH if non-compliant with compression or if preferred.
- Women considered high-risk (presence of major risk factors, multiple minor risk factors) should receive LMWH prophylaxis.
- LMWH is generally preferred, however if unplanned delivery is anticipated consider switching to SQH.
- Chemoprophylaxis should be ordered to be given after the fetal NST each day.

DOSE:

1. Pneumo-boots—no agreed upon consensus regarding minimal time, “may be removed while patient is ambulating, but should be put back on when the patient returns to seated or supine position”

2. Chemoprophylaxis - There are two acceptable doses of LMWH for VTE prophylaxis:
   a. Lovenox 40 mg q d is an accepted and often utilized dose for VTE prophylaxis. The advantage to 40 mg qd is the ability to administer regional anesthesia at 12 hours, as opposed to needing to wait 24 hours with higher doses of LMWH. A disadvantage is this dose has been shown to have a much lower rate of blood levels deemed to be “therapeutic” for VTE prophylaxis. Achieving these blood levels has never been shown to reduce VTE morbidity.
   b. Weight-based dosing should be used (0.5 mg/kg twice daily) in patients greater than 144kg (315lbs) when delivery is not imminent. Weight based dosing is more effective for achieving adequate blood levels in the obese, however may hinder the ability to have regional anesthesia performed if taken within 24 hours.
**Patient Admitted to the Hospital**

Any ONE of the following:
- Morbid Obesity (BMI ≥ 40)
- Any history of VTE not already on anticoagulation

OR

Any TWO of the following:
- Age >40 or <15 years
- Pre-pregnancy obesity (BMI ≥ 30)
- Bed rest
- Medical condition *
- Pregnancy complication **
- History of ART

YES

Recommend Prophylactic Anticoagulation with LMWH or UFH

- > 144 kg
  - Recommend LMWH 0.5 mg/kg twice daily

- < 144 kg
  - Recommend LMWH 40 mg daily

Contraindication to LMWH:
Subcutaneous heparin preferred
- < 20 weeks: 5000 U twice daily
- 20-28 weeks: 7500 U twice daily
- > 28 weeks: 10,000 U twice daily

NO

Recommend pneumatic compression devices (may use LMWH if patient prefers or non-compliant)

*Medical Conditions: (This is not an all-inclusive list)
- Heart Disease
- Lupus
- Renal Disease
- Major Infection
- Cancer
- SLE
- Inflammatory polyarthropathy
- Inflammatory bowel disease
- Nephrotic syndrome
- Type 1 DM with nephropathy
- Sickle cell disease
- Current IVDU
- Smoking
- Gross varicose veins
- Paraplegia
- Other major medical condition

**Pregnancy Complications:
- IUGR
- Preeclampsia
Intrapartum Prophylaxis

- The majority of patients may stop anticoagulation and induce labor within 24 hours.
- Alternatively, may convert from therapeutic or prophylactic LMWH to UFH if delivery is anticipated in select patients.
- Consider Anesthesia consultation prior to intrapartum period to devise mutually agreed plan for anticoagulation.
- Interruption of anticoagulation decreases risk of epidural or spinal hematoma with regional anesthesia. To be considered for regional anesthesia, patients should wait:
  - 12 hours after the last prophylactic dose of LMWH (40 mg per day dose)
  - 24 hours after the last dose of LMWH > 40 mg per day
  - Neuraxial anesthesia okay when receiving 5000 units of UFH q 12 hours
  - If receiving greater than 10K units of UFH per day, neuraxial anesthesia may be used 4 hours after last dose or with PTT < 40, 2 hours after last dose. Protamine sulfate may be used in select emergent cases with expert consultation.
- Recommendations from UC Health “Institution recommendations for using anticoagulant agents and coagulation status in adult patients undergoing neuraxial anesthesia procedures”
- Continue pneumatic compression devices when anticoagulation has been discontinued.

Cesarean delivery

- Pneumatic compression devices recommended before start of cesarean delivery for all patients.
- Decision for UFH or LMWH at the time of cesarean section should be based on individual risk assessment of additional risk factors.
- Although cesarean delivery increases risk of VTE, universal anticoagulation is not recommended.
  
  Low risk patients:
  - Pneumatic compression devices may be preferred to unfractionated heparin because of risk of bleeding complications.
  - Pneumatic compression devices have been found to be cost effective.

  High risk patients:
  - Individual risk assessment may require thromboprophylaxis with pneumatic compression devices and/or LMWH
  - Patients with one more more risk factors for venous thromboembolism should be considered for postpartum prophylaxis with LMWH

Postpartum Prophylaxis

- Anticoagulation should be resumed no sooner that 6 hours after SVD, 12 hours after CD. American Society of Regional Anesthesia recommend at least 2 hours from epidural removal and resumption of prophylaxis.
- Pneumatic compression devices should be left in place until anticoagulation is restarted.
- Select patients on antepartum prophylaxis who continue to have significant risk factors for VTE should receive postpartum prophylaxis for 6-12 weeks.
VTE Prevention: Postpartum (in hospital)

OR 2 or more risk factors below are present:

- Cesarean delivery
- Hemorrhage (if stable after 12-24 hours)
- Hysterectomy
- General anesthesia
- Postpartum infection
- Age > 40 or < 15 years
- Pre-pregnancy obesity (BMI > 30)
- Bed rest
- Any Thrombophilia
- Medical or pregnancy complications

Prophylactic LMWH or UFH until discharge

**Legend:** Recommendations for prophylaxis are based on guidelines from the Royal College of Obstetricians and Gynaecologists.
